Radioactive Isotope Studies with Metalosate® Products

By Jeremy O'Brien

In today's very competitive micronutrient market, we are often asked what sets our products apart from the others and why are they better than anything else available. The answers to these questions are not short, and they involve many aspects of providing not only superior products to our customers, but also involve providing service.

Albion has been involved in plant nutrition for over 20 years. In that period of time, we have learned many things and have always been very dedicated to performing ongoing research with the Metalosate® products. One series of research projects in the early days of development of the Metalosate® products dealt with radioactive isotopes. The following text is taken from a paper co-written by Harvey Ashmead, Ph.D. and Stephen Ashmead, M.S. and presented at an international conference on plant nutrition in 1995.

“Albion has conducted research in cooperation with many universities involving radioactive isotopes. Experimental research involving isotopes often provide the basis of proof of a compound's effectiveness.

Such is the case with Albion's metal amino acid chelates. In all of Albion's radioisotope trials, the radioisotope label is chelated with the same ligands as the rest of the chelate and then administered to the organism.

In each case any label that appears in the organism is directly attributable to the chelate. In addition, any physiological function that is discernable with the radiolabel can be directly attributable to the chelate.

In conjunction with Weber State University (Ogden, Utah), Albion has conducted a series of radioisotope trials in various plants which show the translocation of Albion's chelates within the plant tissues in greater quantities than inorganic salts and ethylenediaminetetra-acetic acid (EDTA) salts. For example ⁵⁹Fe was applied as a topical solution to tomato plant leaves as an amino acid chelate, a sulfate or and EDTA chelate. After application, the leaf was thoroughly

Table 1.
Absorption of Foliar Applied ⁵⁹Fe from Different Sources by Tomato Plant Leaves (ccpm/mg*)

Plant Part	Metalosate®	EDTA	Sulfate
Treated leaf	43.10	26.60	29.40
Adjacent leaf	0.20	0.10	0.20
Treated stem	0.30	0.03	0.14

**Corrected counts of radioactivity per minute per milligram of fresh tissue.*

washed and assayed for ⁵⁹Fe. In addition, the leaf adjacent to the treated leaf and the stem of the treated leaf were also analyzed for ⁵⁹Fe content. The results are summarized in Table 1., and they indicated greater absorption with Albion's chelates.

Albion Advanced Nutrition has conducted additional radioisotope research using ⁶⁵Zn, ⁵⁴Mn, and ⁵⁹Fe in cotton, soybean, tomatoes, and corn plants with similar results and distributions.”

To get the most value for money spent, we recommend that Metalosate® products be your product of choice. ☺
